What is Social Science?

social science

noun

noun: **social science**

the scientific study of human society and social relationships.

- a subject within the field of social science, such as economics or politics.

plural noun: **social sciences**

Social Science

Surveys

Interviews

Participant observations

Document analysis

...

What is complexity?

complexity

/kəm'pleksəti/ 

noun

the state or quality of being intricate or complicated.

"an issue of great complexity"

synonyms: complication, problem, difficulty, twist, turn, convolution, entanglement; [More](#)

- a factor involved in a complicated process or situation.

plural noun: complexities

"the complexities of family life"

Add another family member

- Write down 5 reasons

What is complexity?

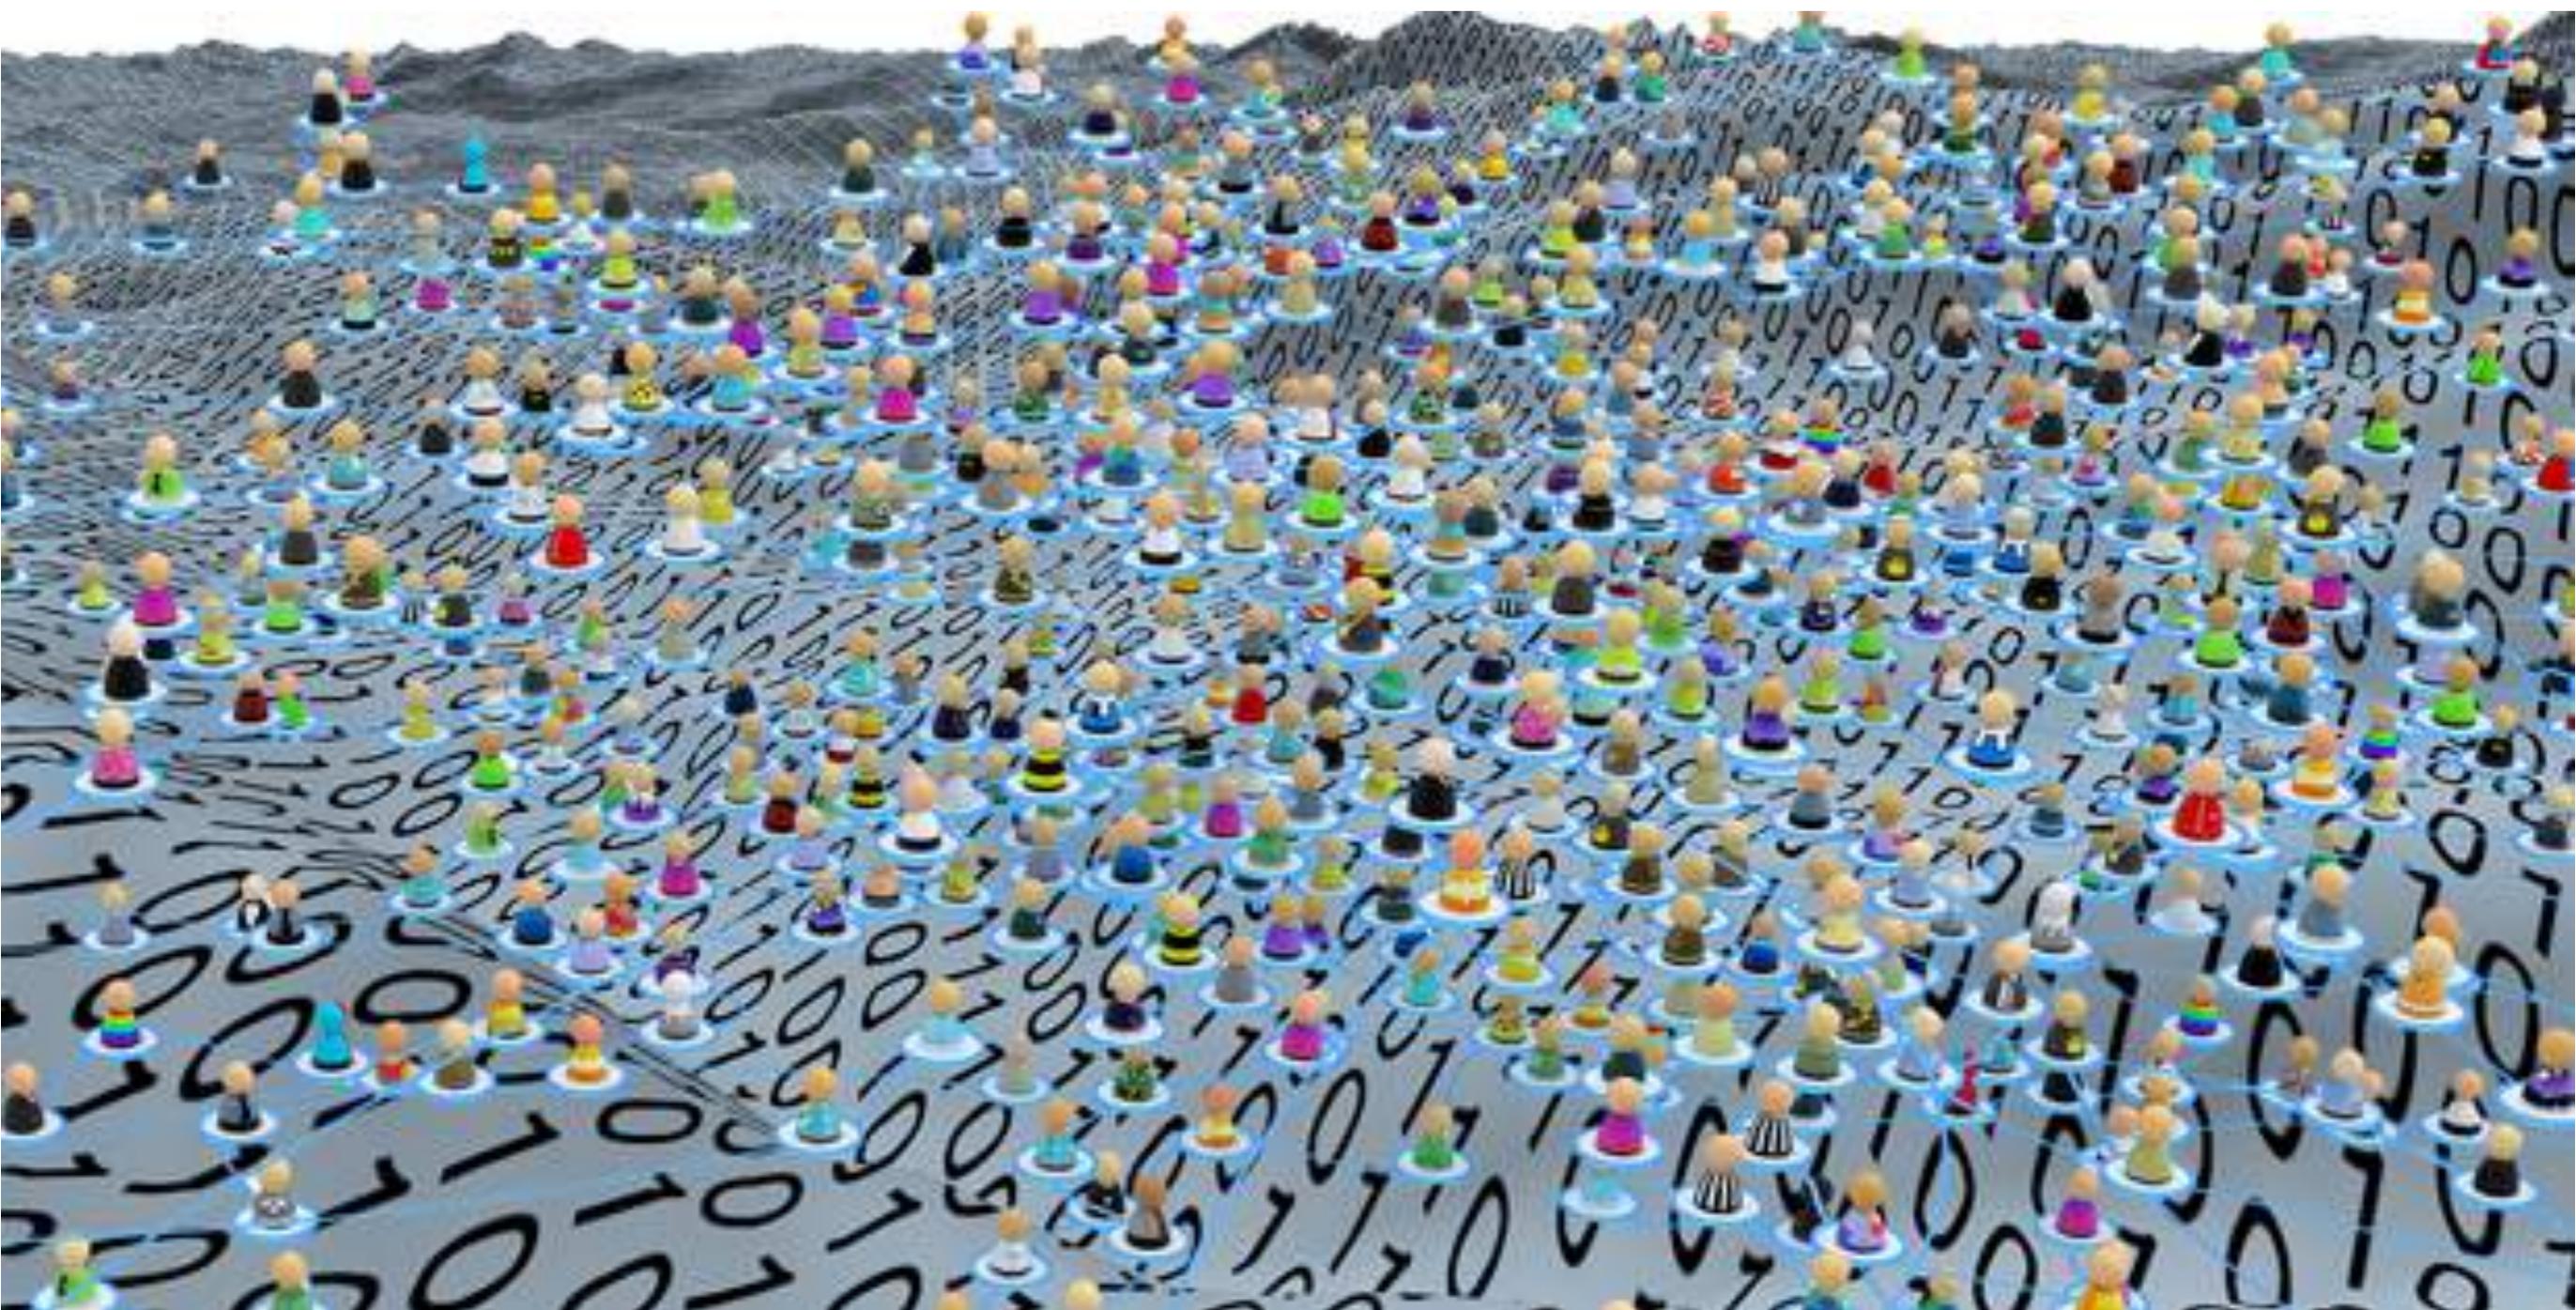

complexity

/kəm'plɛksəti/ 

noun

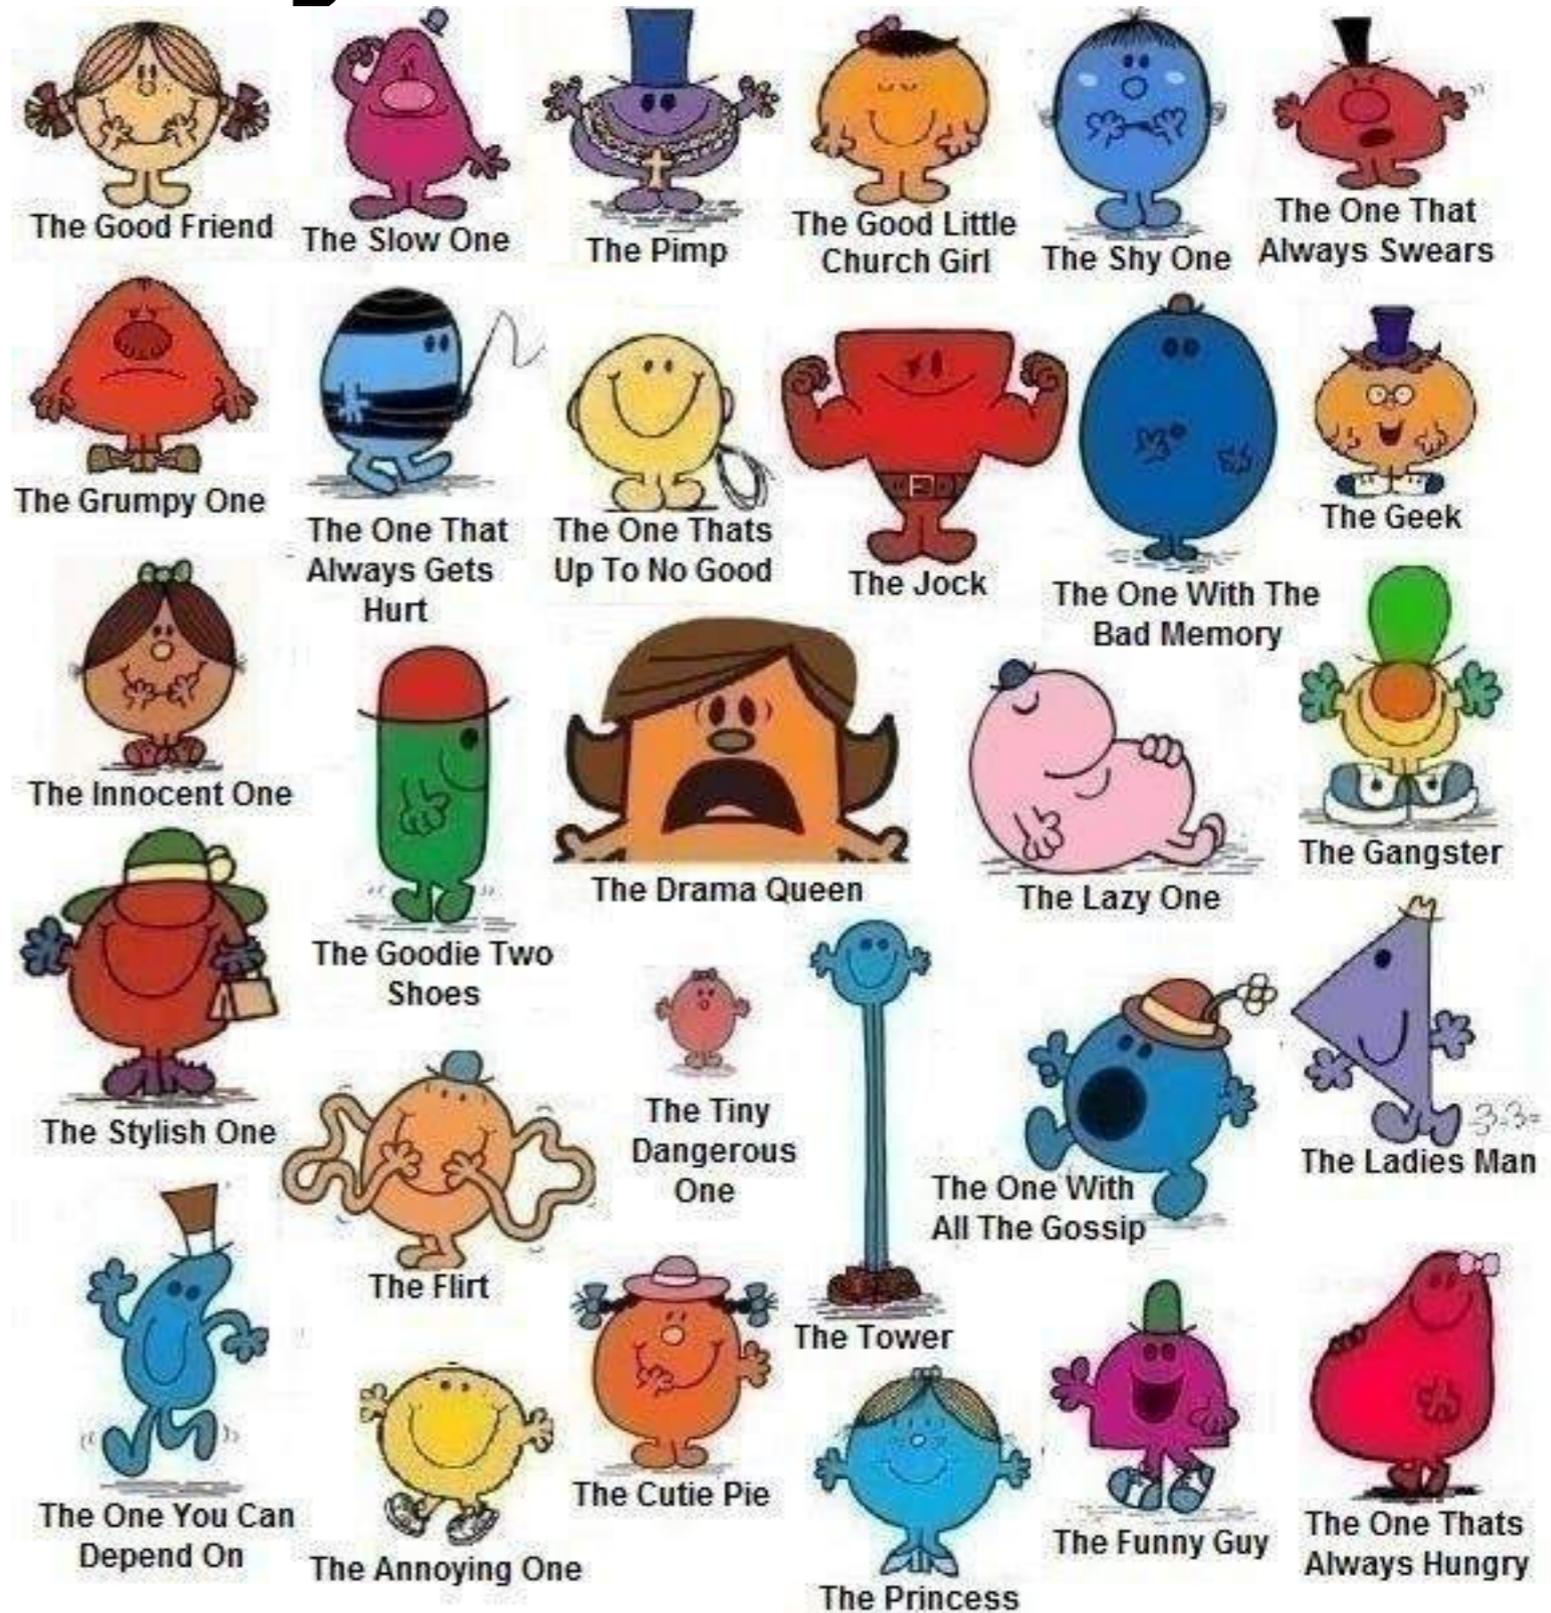

- **a property of a system (of systems)** resulting from the parts and the relationships between system parts. Complexity leads to the impossibility to partition the system to analyse parts in isolation.

no clear solution

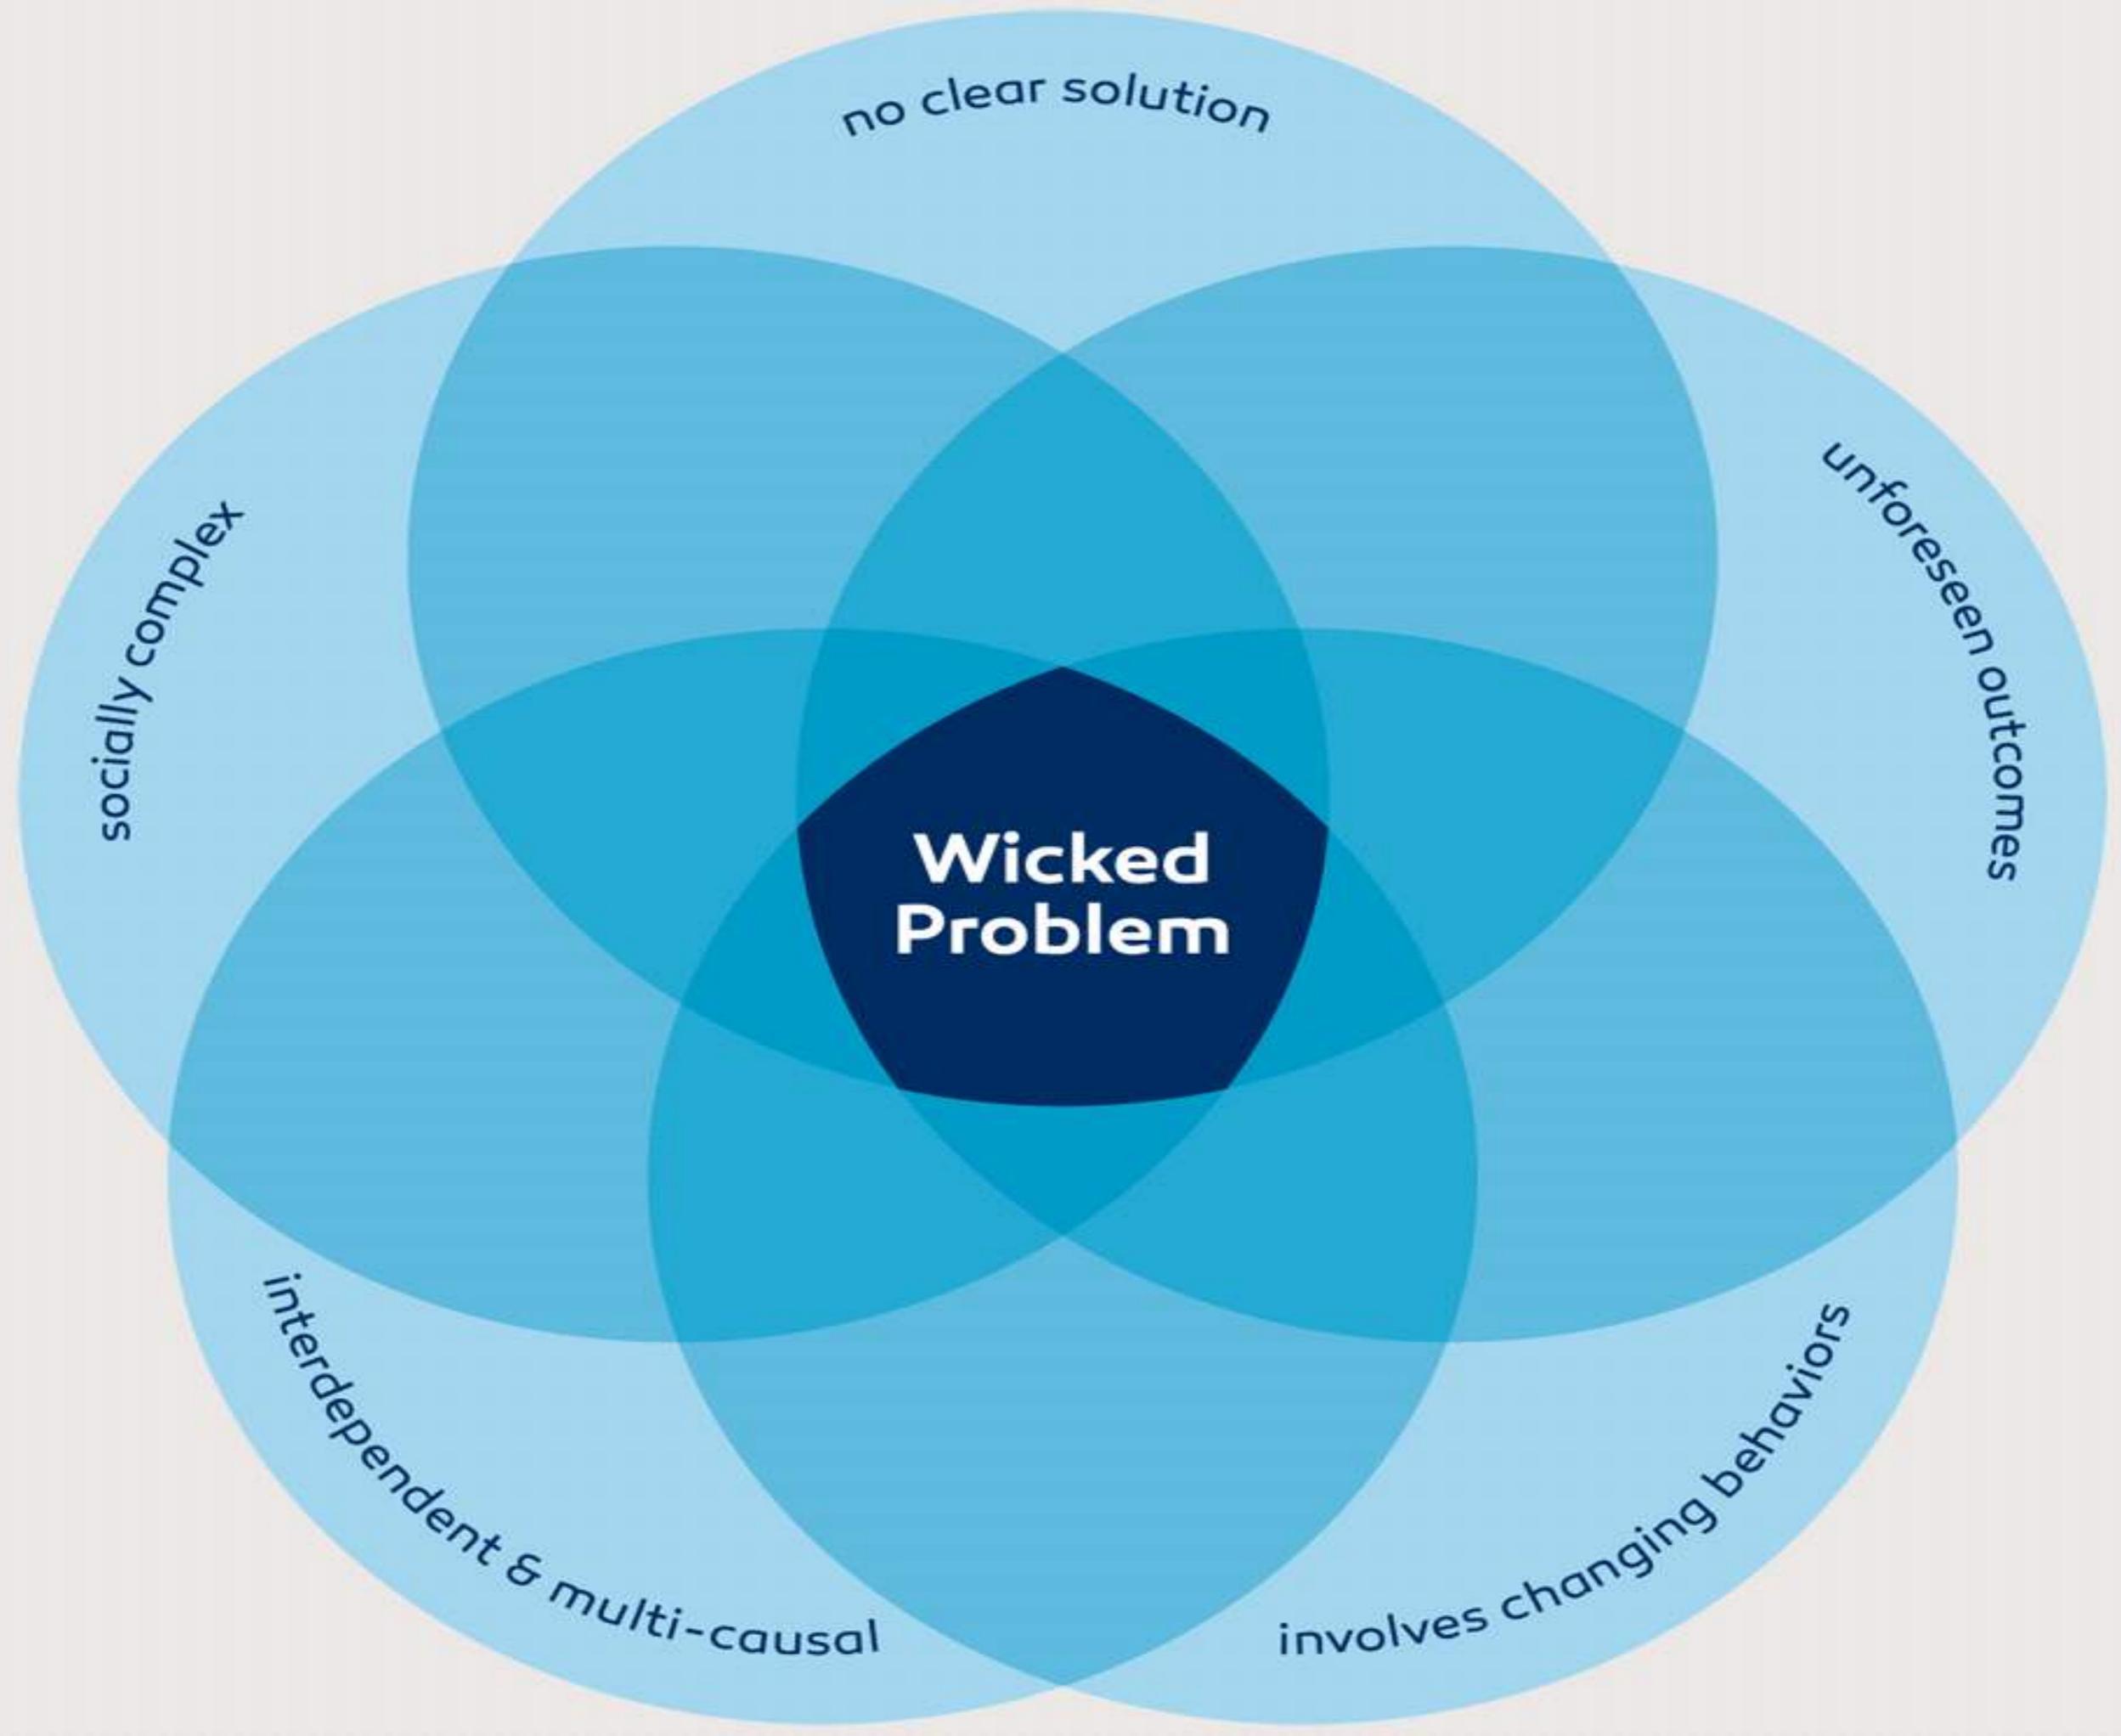

unforeseen outcomes

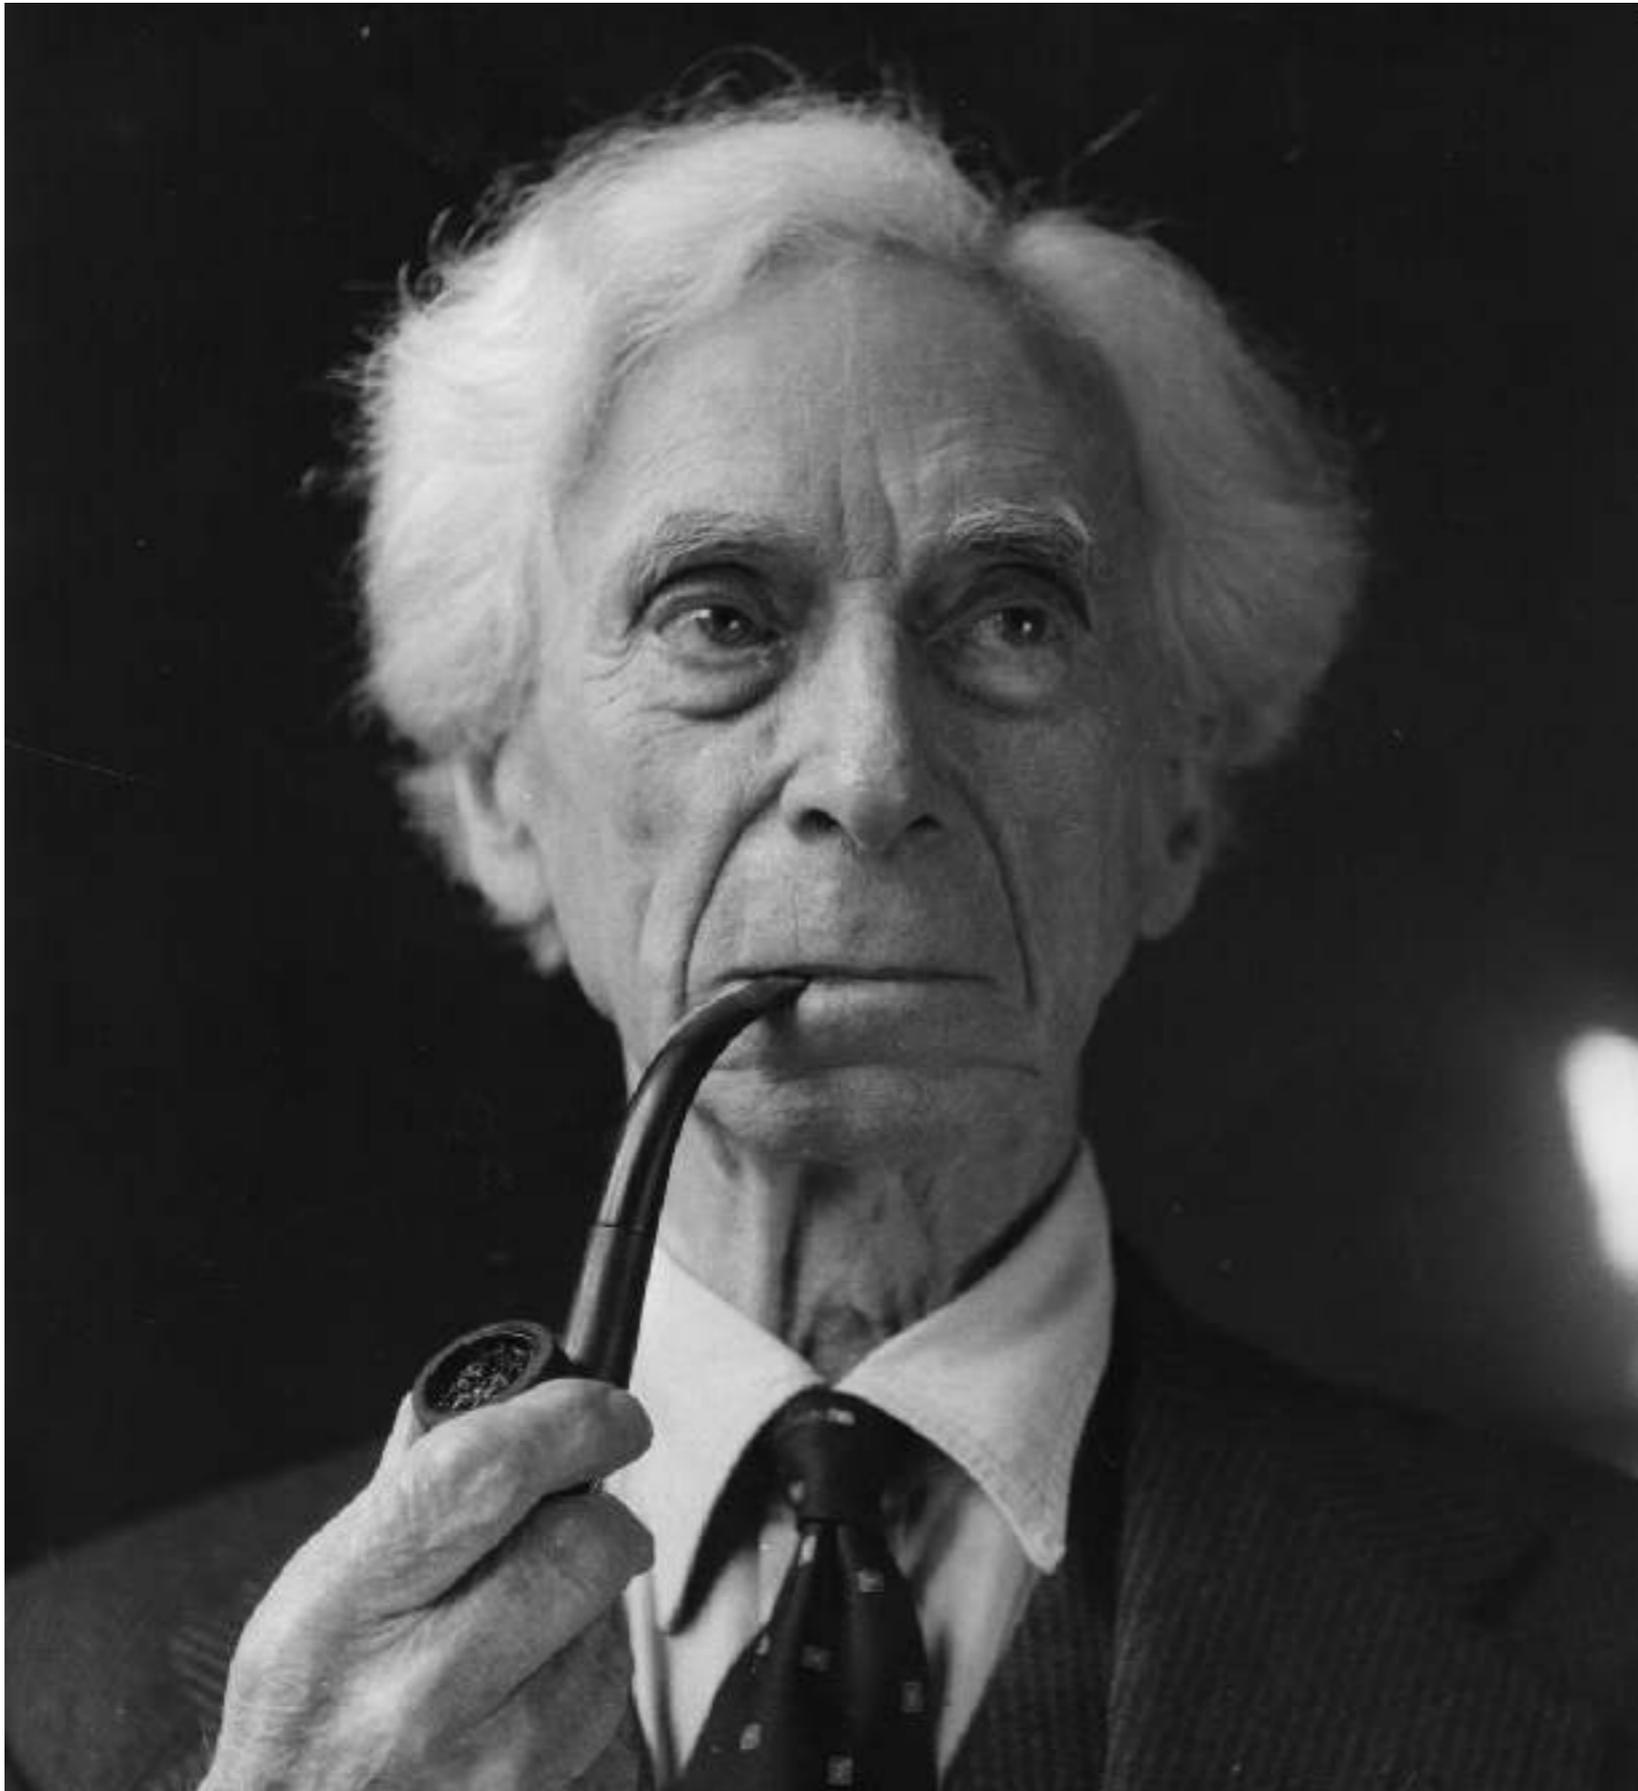

Wicked Problem

socially complex

involves changing behaviors

interdependent & multi-causal

“The law of causality, I believe, like much that passes muster among philosophers, is a relic of a bygone age, surviving, like the monarchy, only because it is erroneously supposed to do no harm.

— Bertrand Russell

X is a necessary and or sufficient condition of Y

Ceteris Paribus - all things being equal
- but in a complex system there is no
way to isolate for ceteris paribus.

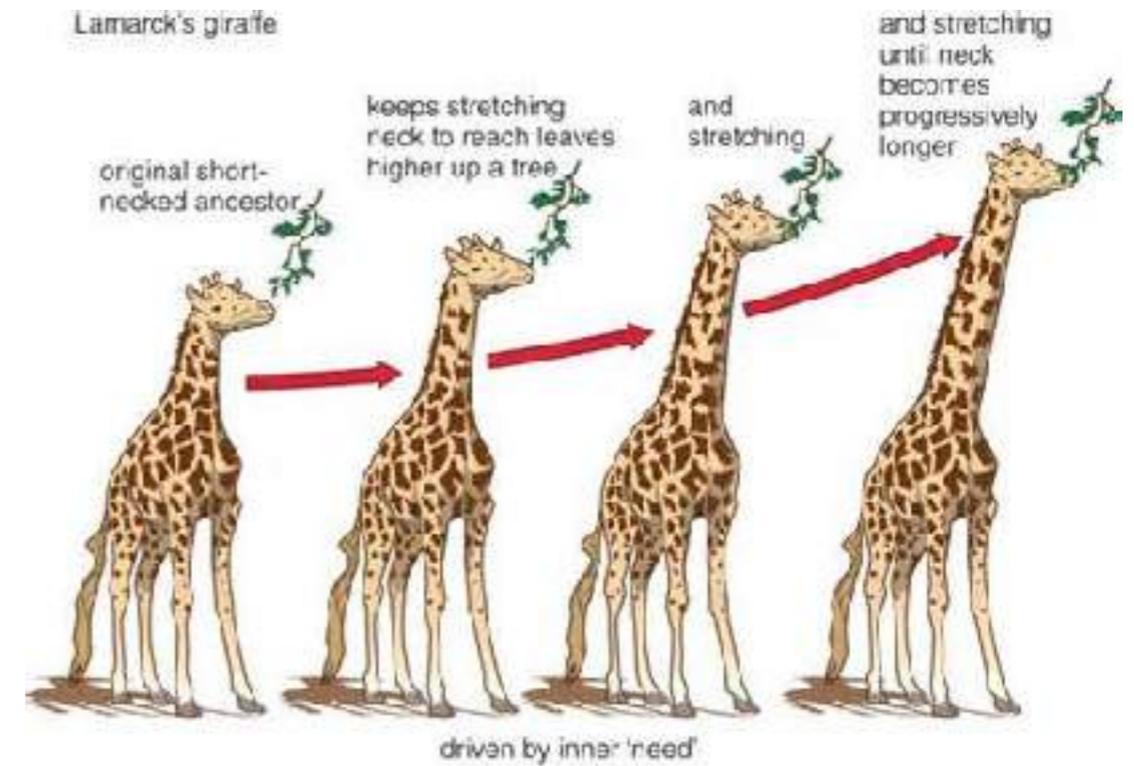

If X had not occurred, Y would not have occurred.

Multiple Causes - you don't even have to go complex to recognise multiple causes.

The conditional probability of Y given X is different from the absolute probability of Y ($P(Y|X) \neq P(Y)$).

Spurious attribution.

There is a causal mechanism leading from the occurrence of X to the occurrence of Y.

Telling the causal story - but how do we make sure it is the right one?

Complexity Sensitive Social Science Methods

- **Qualitative Comparative Analysis (QCA)**
- **Process Tracing**
- **Dependency Models/Bayesian Networks**
- **Agent-Based Modelling**

QCA

- Grounded on **multiple-conjunctural** causality
 - A.k.a. configurational, **chemical** causation
- **Configurations** of factors are causally related to outcomes, not single causes
- Even when you can disentangle the effect of a single cause, you can't take it away from its context (the other causes it's combined with)
 - Hence "conjunctural"
- **Causal asymmetry**: causes can be only necessary, only sufficient, both or neither
 - INUS and SUIN causes

Causal asymmetry, causal diversity

- If you light a match, you need the surface to be dry
 - Fire powder AND dry surface AND the movement = FIRE
- While the above is sufficient, it's not necessary: there are other ways to get fire (hence **multiple**)
 - Lighter: metal mechanism using flammable liquid (butane)
- **INUS**: some causes are necessary in a specific context but not in others
 - The movement when you have a match AND the right dry surface
 - Lighters only work with specific liquids
- **SUIN**: equivalent requirements. Different factors are good enough but one of these is required
 - A dry surface is required, but different types of dry surface do the job

Generative/Mechanism-Based Causality

- Correlations and associations are not good enough
- Open the “black box” and investigate the “inner workings” that “generate” the effect
- High degree of precision is required
- “Magnifying lens”
- Ideally we want to observe the effect while it is being “caused”
- If not possible, we seek evidence that a specific process took place...

Process Tracing (with Bayesian Updating)

- Grounded on Generative Causality
 - A.k.a. mechanism-based: how and why the outcome occurred, what generated the outcome
 - The mechanism representation can take several forms
 - The whole system, some of the cogs / wheels, a process
- In PT it is often represented as a **process**
 - But that's just because it's easier to apply the method!
- Clear distinction between **theory**, **data**, and our levels of **confidence**
- **Rigorous / replicable** way of dealing with **uncertainty**
- Our confidence can be estimated with the **Bayes** formula

Basic elements of Process Tracing with BU

- Theory / mechanism / explanation / statement = **ontological** object
 - Could be true, could be false. It's usually a statement about how things work
- Our **confidence** that the theory / statement, etc. is TRUE (or false)
- Two levels of confidence: one before observing empirical data, and one after
 - **Prior, Posterior** (in Bayes formula the Posterior is a function of the Prior et al.)
- Empirical **data** / observations
- Organises data into categories, on the basis of two characteristics:
- **Probative value** (strength, weight of evidence);
- Whether data **confirms** / strengthens or disconfirms / **weakens** theory

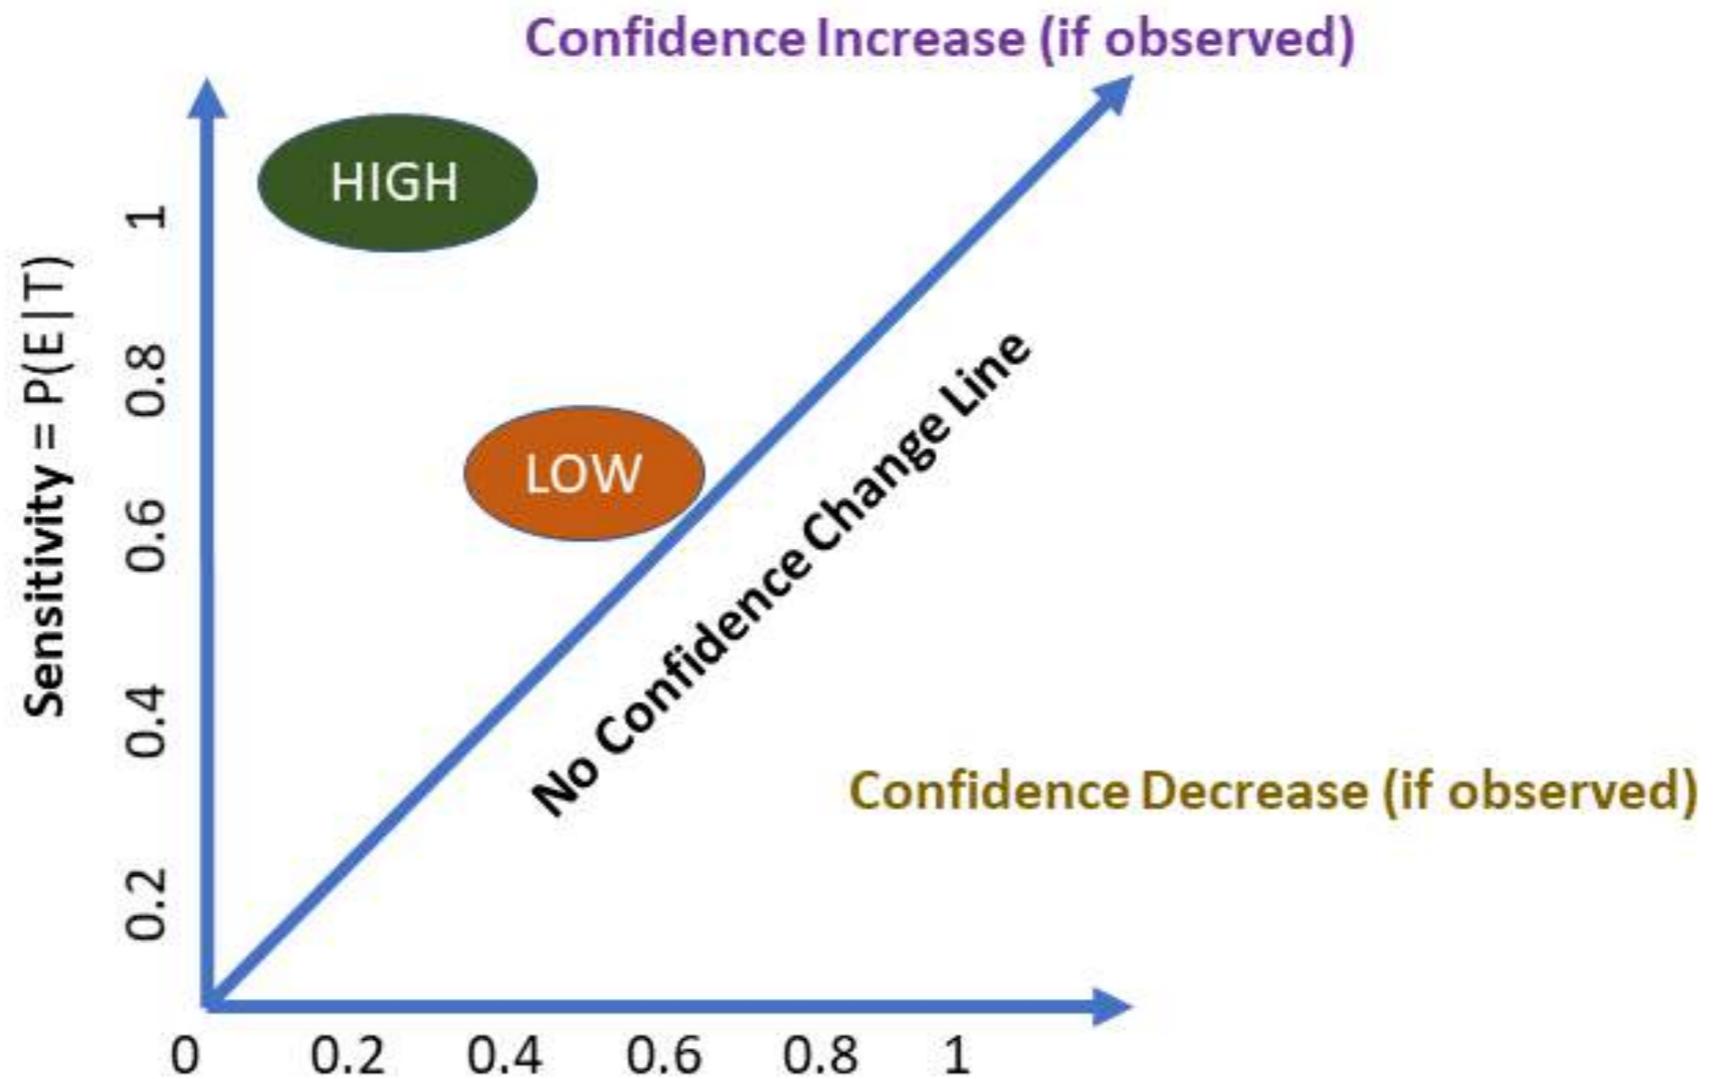

Quali-quant confidence translator

| | |
|--|----------------|
| Practically certain that () is true | 0.99+ |
| Reasonably certain that () is true | 0.95 – 0.99 |
| Highly confident that () is true | 0.85 – 0.95 |
| Cautiously confident that () is true | 0.70 – 0.85 |
| More confident than not confident that () is true | 0.50 – 0.70 |
| Neither confident nor not confident that () is true (or false) – no idea | 0.5 |
| More confident than not confident that () is false | 0.30 – 0.50 |
| Cautiously confident that () is false | 0.15 – 0.30 |
| Highly confident that () is false | 0.05 – 0.15 |
| Reasonably certain that () is false | 0.01 – 0.05 |
| Practically certain that () is false | Less than 0.01 |

Process Tracing tests

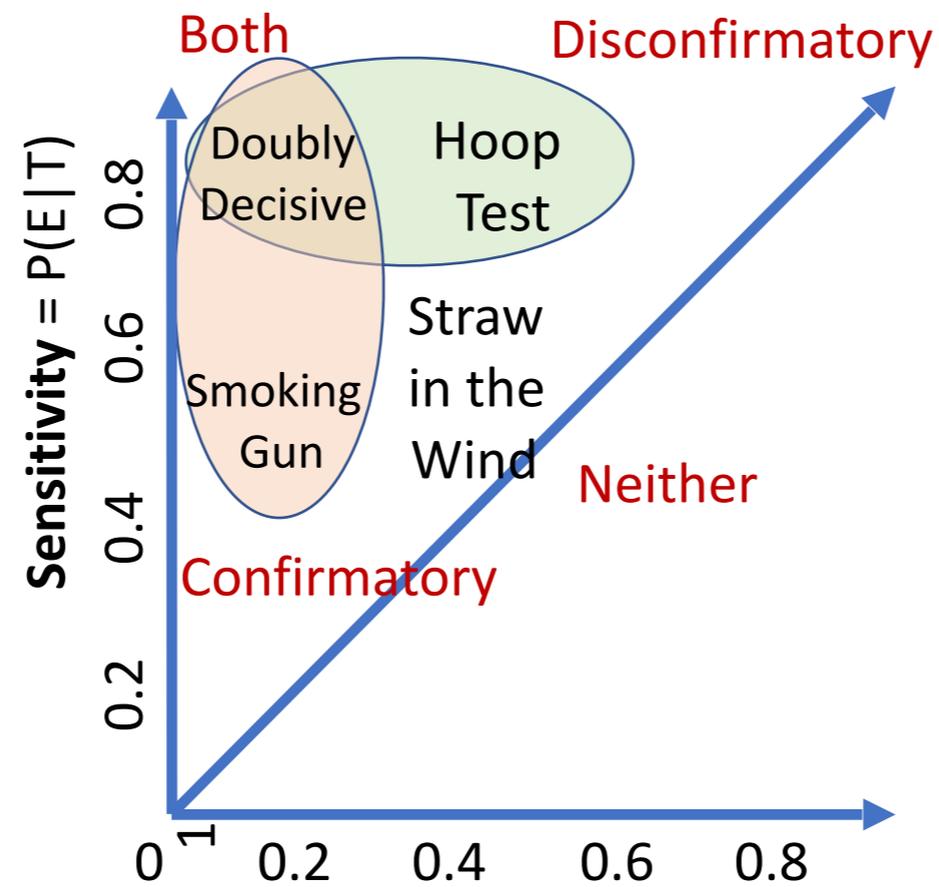

- **Three strong tests (with high probative value)**
 - Smoking Gun
 - Hoop Test
 - Doubly Decisive
- **One weak test (with low probative value)**
 - Straw-in-the-Wind
- **The Smoking Gun:** if observed, it CONFIRMS the theory but, if not observed, does NOT WEAKEN it
- **The Hoop Test:** if not observed, it WEAKENS the theory but if observed, does NOT CONFIRM it
- **The Doubly Decisive:** if observed, it confirms; if not observed, it weakens.

Likelihood Ratio = Sensitivity / Type I Error

Type I Error = $(1 - \text{Specificity}) = P(E|\sim T) = 1 - P(\sim E|\sim T)$

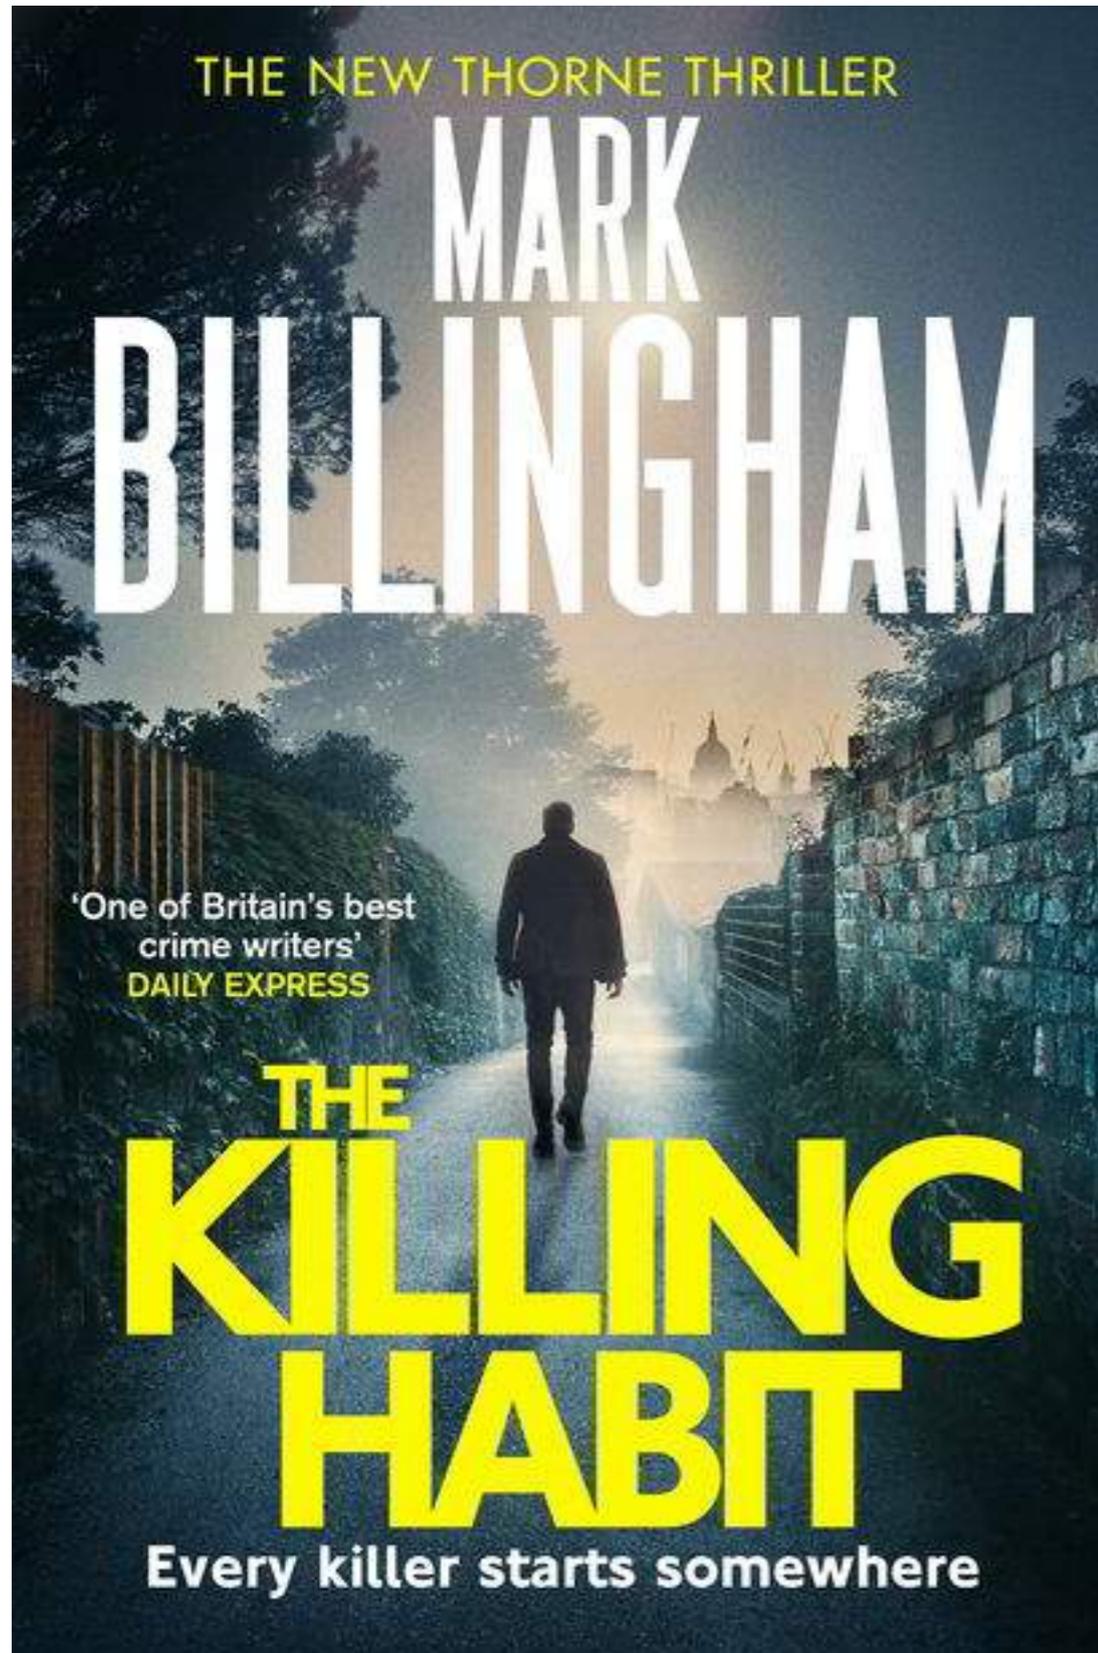

Likelihood Ratio = Sensitivity / Type I Error

Type I Error = $(1 - \text{Specificity}) = P(E|\sim T) = 1 - P(\sim E|\sim T)$

Relation with the Confusion Matrix

| | | Reality (ontological reality) | | | |
|-------------------------------|---|--|---|--|---|
| | | The Contribution Claim (CC) is TRUE | The Contribution Claim (CC) is FALSE | | |
| Evidence (observable reality) | Evidence (E) showing the Contribution Claim (CC) is TRUE | True Positive (A) | False Positive (B) | Positive Predictive Value = $A / (A + B)$ | False Discovery Rate = $B / (A + B)$ |
| | Evidence (E) showing the Contribution Claim (CC) is FALSE | False Negative (C) | True Negative (D) | False omission rate = $C / (C + D)$ | Negative Predictive Value = $D / (C + D)$ |
| | | True positives rate = Sensitivity = $1 - \text{Type II error} - A / (A + C)$ | False positives rate = $1 - \text{Specificity} = \text{Type I error} - B / (B + D)$ | Likelihood ratio = $\text{TPR} / \text{FPR} = \text{Sensitivity} / \text{Type I error}$ | |
| | | False negatives rate = Type II error = $1 - \text{Sensitivity} - C / (A + C)$ | True negatives rate = Specificity = $1 - \text{Type I error} - D / (B + D)$ | | |

“ Everyone always says there’s nothing worse than the jigsaw with a single piece missing, but a jigsaw that is *really* useless is one that doesn’t come in a box. One that hasn’t got a picture.

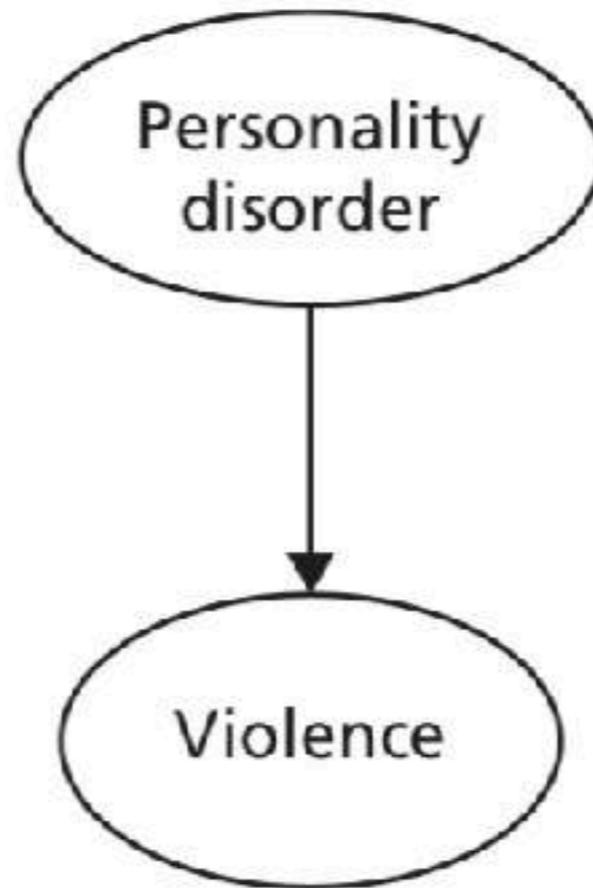

– *Inspector Tanner*

Getting the Picture

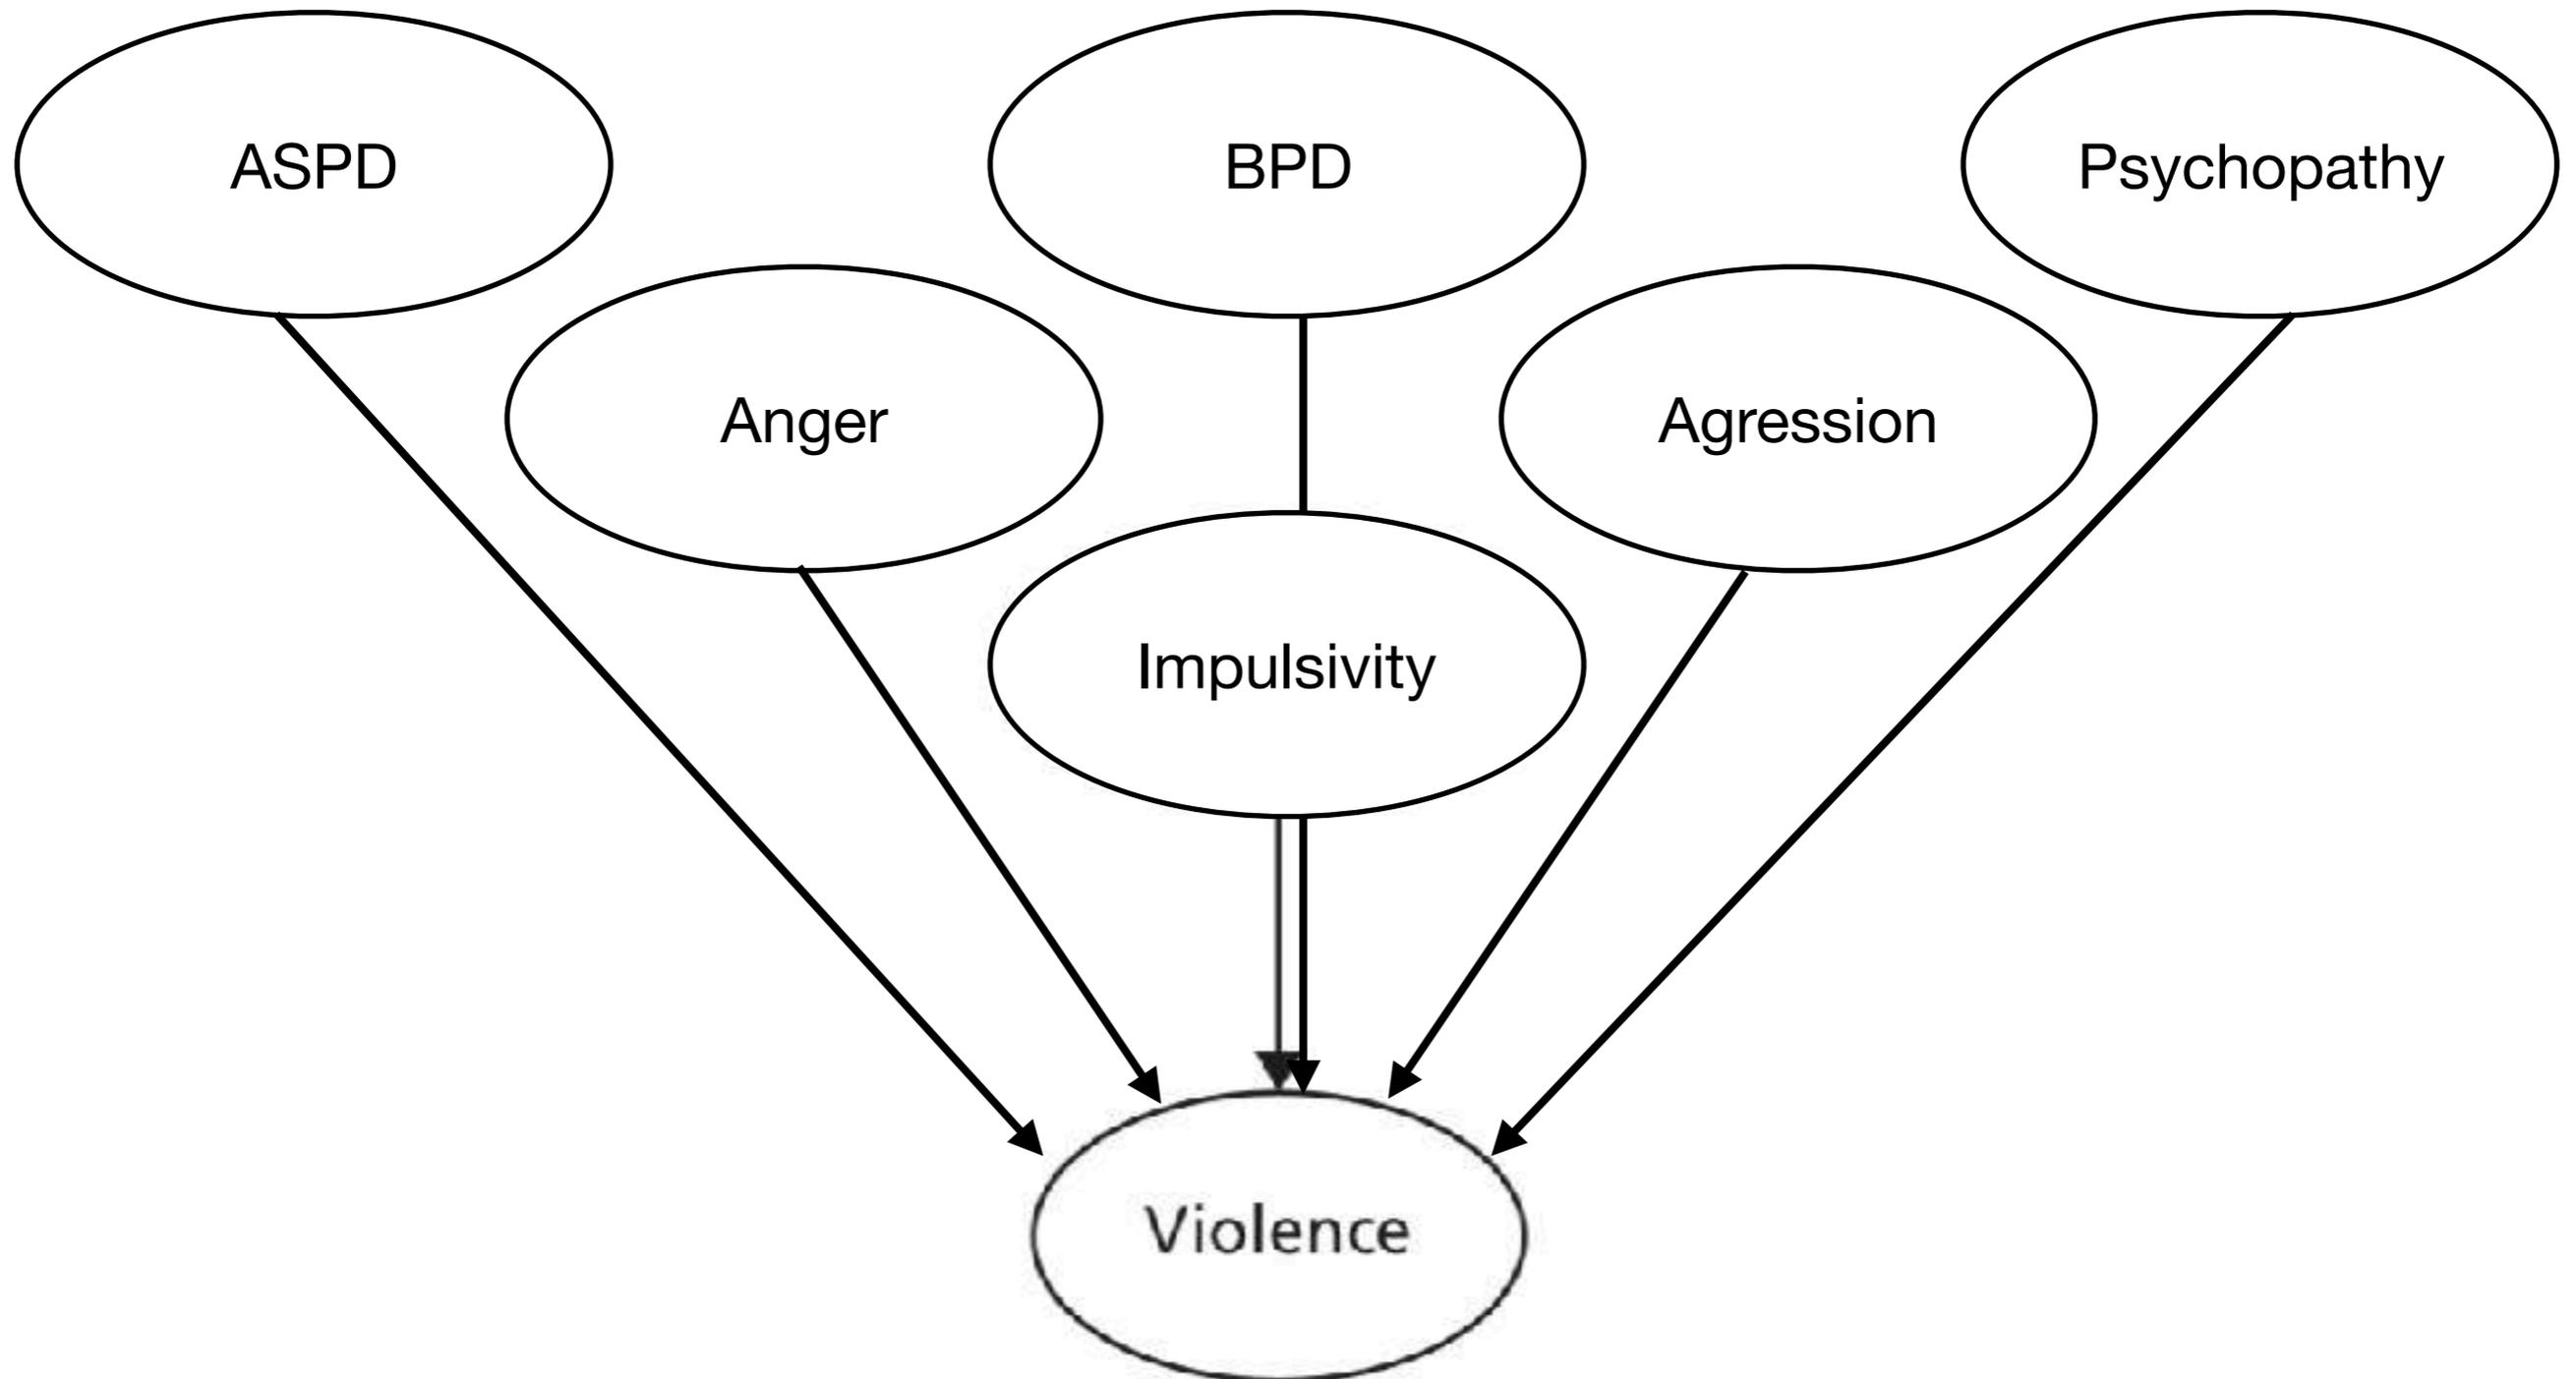

Understanding a system will help to make better policy, even without the possibility of prediction.

“Uncertainty is an uncomfortable position. But certainty is an absurd one.”

– Voltaire

Summing Up

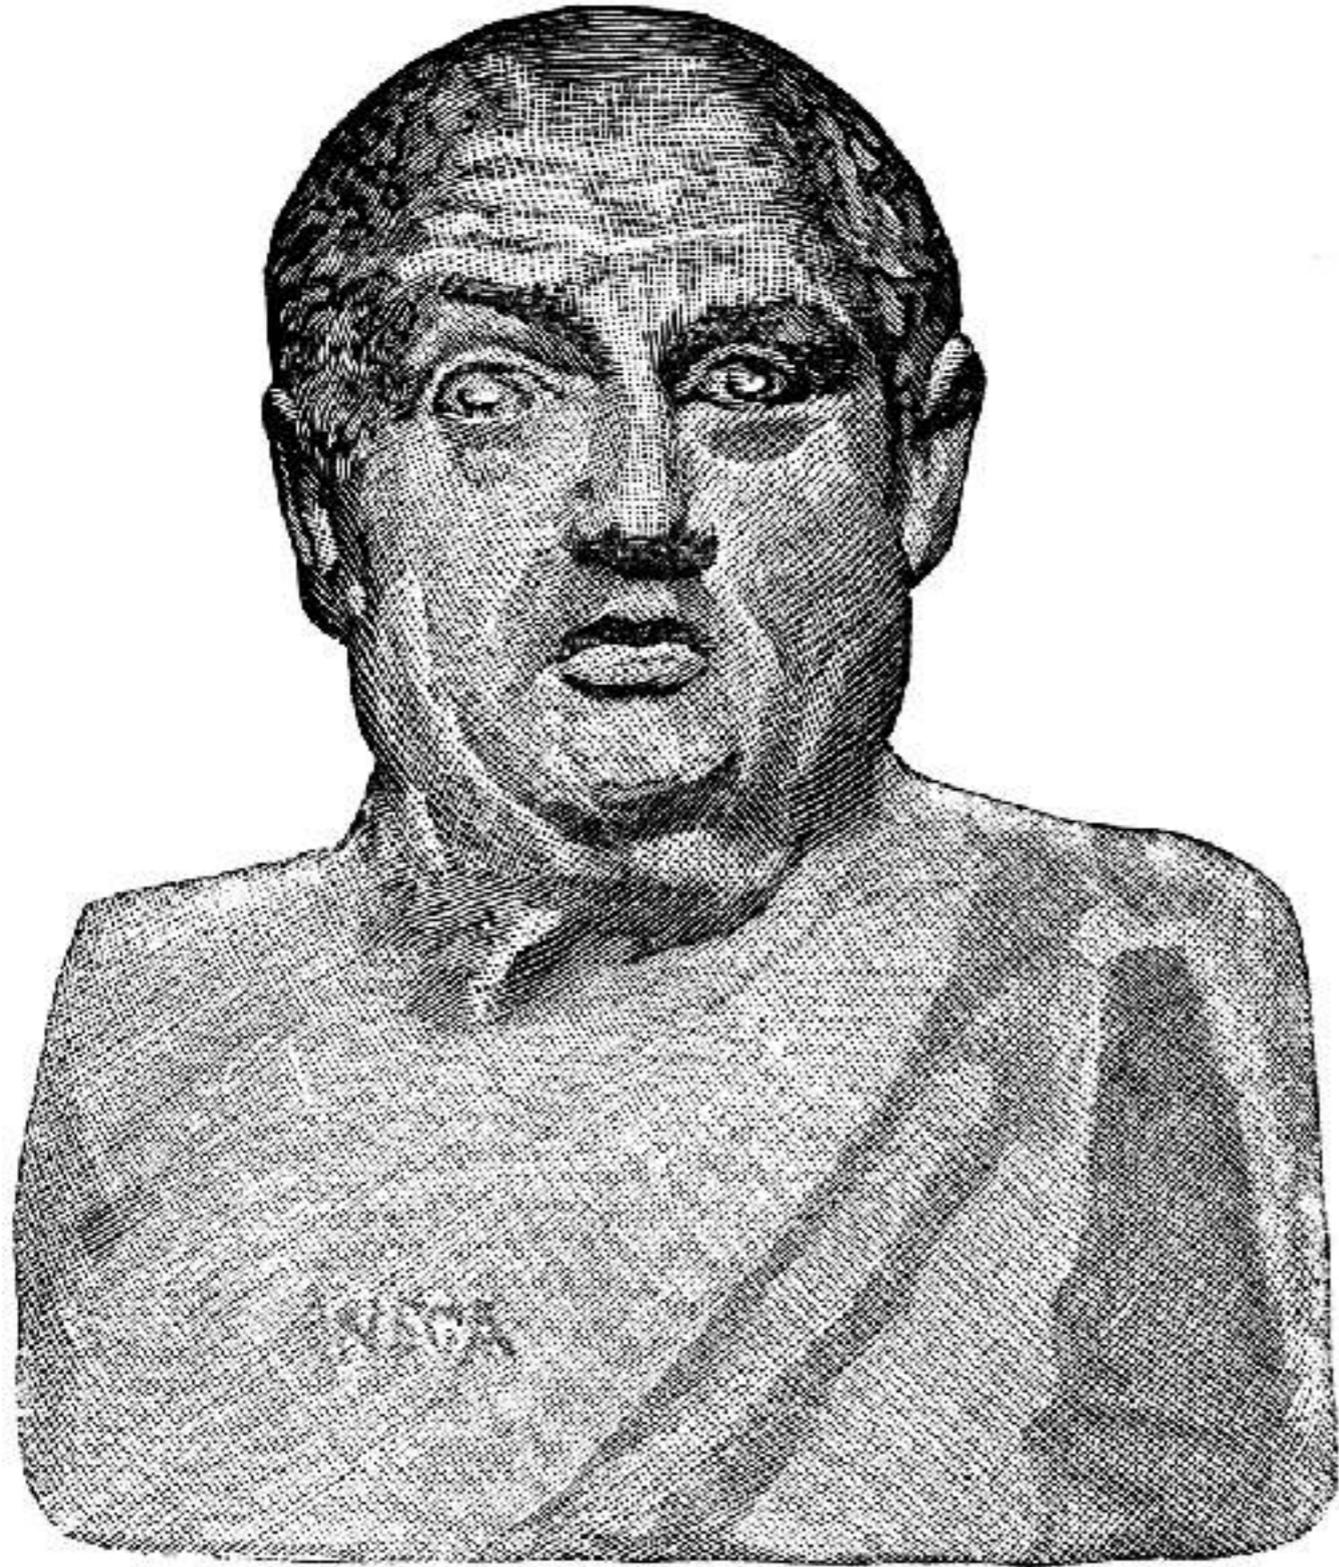

Society is a complex system

**If we want to understand society
we need to understand causality
- in the context of all the other
complex features.**

**There are some (cool) methods
that grapple with that problem.**

Questions?

“If you judge, investigate.”

–Seneca
